Received August 14, 2000

We consider a multi-component system of charged particles that interact via a general many-body potential, and calculate the reduced distribution functions from the Bogoliubov-Born-Green-Kirkwood-Yvon hierarchy of equations in the form of a screened virial expansion through second order.

Key words: *charged particles, distribution function, BBGKY hierarchy, virial expansion*

PACS: 05.20.-y

1. Introduction

The calculation of the spatial distribution of particles in a given physical system with defined microscopic interactions belongs to the most fundamental problems in the statistical theory of the equilibrium properties of matter. If the particle species of the system and the global features of the relevant interaction potentials are known, one can derive the appropriate Bogoliubov-Born-Green-Kirkwood-Yvon (BBGKY) hierarchy as the basic set of equations for the distribution functions (see, e. g., [1]). Here, it is of particular interest to state whether these potentials are short-ranged, long-ranged, or even have components of both types, since as soon as long-range interaction is involved, the BBGKY hierarchy must be screened in a suitable way to insure convergence of the results.

The present paper deals with a multi-component system of classical particles that may differ in their mass, charge, and internal structure, and interact through a very general potential describing the two-body Coulomb forces, and arbitrary short-range forces between two and more particles as well. In the first part, we

*E-mail: torsten.kahlbaum@berlin.de

fully specify the steps in the derivation of the BBGKY hierarchy for this system, starting from the definition of the reduced distribution function and proceeding to a decoupled set of differential equations for the coefficients in its virial expansion, where the adopted screening procedure was proposed by Schmitz [2,3]. The second part then presents details of getting analytic solutions of these equations for the first and the second-order virial coefficients which are given as multiple integrals over various combinations of the screened Coulomb potential and generalized Mayer cluster functions.

It should be mentioned that the exact determination of the virial expansion of the distribution function up to a certain order is only the starting-point in our whole programme to calculate the thermodynamic properties of non-ideal quantum plasma at low densities within the framework of the effective-potential approach [4,5], and a series of further papers on this subject will appear in the near future. For the sole purpose of obtaining the corresponding Helmholtz free energy, however, a formal treatment of the screened BBGKY hierarchy in terms of Mayer functions is quite sufficient, and hence we made no efforts to explicitly evaluate the integrals in the virial coefficients for a special choice of the short-range potentials as, e. g., hard-core interaction [6]. A brief account of the present results has been already published [7].

2. The screened BBGKY hierarchy

Let us examine a fluid mixture in the volume V at temperature T consisting of a total number of N charged particles with spatial coordinates $\{\mathbf{r}_i\}$ ($i = 1, \dots, N$) whose species are denoted by either a_1, a_2, \dots or a, b, \dots , so that $N = \sum_a N_a$, where N_a is the number of particles of species a . In order to shorten our notation, we only retain all subscripts for the species but omit the coordinates which always means that, for any function, $\mathcal{F}_{a_1 a_2 \dots} \equiv \mathcal{F}_{a_1 a_2 \dots}(\mathbf{r}_1, \mathbf{r}_2, \dots)$. The interaction between the N particles is described by the general many-body potential $w_{a_1 \dots a_N}$ [8] made up of all two-, three-, \dots , N -particle contributions $u_{ab}, u_{abc}, \dots, u_{a_1 \dots a_N}$ respectively,

$$w_{a_1 \dots a_N} = \sum_{i < j = 1}^N u_{a_i a_j} + \sum_{i < j < k = 1}^N u_{a_i a_j a_k} + \dots + u_{a_1 \dots a_N}. \quad (1)$$

This interacting multi-component system will be treated with the conventional methods of classical statistics, and the specific objective of our work is to relate the spatial distributions of the particles with the irreducible, or component, potentials $u_{a_1 \dots a_\lambda}$ ($\lambda = 2, 3, \dots, N$) in equation (1). We begin the calculation by making a random selection of s particles from the system, $2 \leq s < N$, for which we define the reduced distribution function $f_{a_1 \dots a_s}$ as an integral over the exponential of the total, or direct, potential $w_{a_1 \dots a_N}$ with respect to the coordinates of the $N - s$ remaining particles,

$$f_{a_1 \dots a_s} = \frac{V^s}{Q_N} \int d\mathbf{r}_{s+1} \dots d\mathbf{r}_N \exp(-\beta w_{a_1 \dots a_N}). \quad (2)$$

$\beta = 1/k_B T$ is the inverse temperature, and the well-known configuration integral

$$Q_N = \int d\mathbf{r}_1 \dots d\mathbf{r}_N \exp(-\beta w_{a_1 \dots a_N}) \quad (3)$$

in the denominator of the prefactor in equation (2) guarantees the normalization of the distribution to V^s , $\int d\mathbf{r}_1 \dots d\mathbf{r}_s f_{a_1 \dots a_s} = V^s$, i. e., $f_{a_1 \dots a_s}$ is a dimensionless function.

In accordance with the separation of the N particles into s and $N-s$ particles, the total interaction potential, equation (1), can be decomposed into the contributions $w_{a_1 \dots a_s}$ from the s -particle system and $w_{a_{s+1} \dots a_N}$ from the $(N-s)$ -particle system, and the sum of contributions from the mutual interactions between these two systems,

$$w_{a_1 \dots a_N} = w_{a_1 \dots a_s} + w_{a_{s+1} \dots a_N} + \sum_{\alpha=1}^{N-s} w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(\alpha)}, \quad (4)$$

where $w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(\alpha)}$ is the composite potential for the interaction between all the s particles and α particles from the $(N-s)$ -particle system which starts with a $(1+\alpha)$ -particle contribution and ends with an $(s+\alpha)$ -particle contribution, $\alpha > 0$,

$$w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(1)} = \sum_{i=1}^s \sum_{\mu=s+1}^N u_{a_i a_\mu} + \sum_{i < j=1}^s \sum_{\mu=s+1}^N u_{a_i a_j a_\mu} + \dots + \sum_{\mu=s+1}^N u_{a_1 \dots a_s a_\mu}, \quad (5)$$

$$w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(2)} = \sum_{i=1}^s \sum_{\mu < \nu=s+1}^N u_{a_i a_\mu a_\nu} + \dots + \sum_{\mu < \nu=s+1}^N u_{a_1 \dots a_s a_\mu a_\nu}, \quad (6)$$

\vdots

$$w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(N-s)} = \sum_{i=1}^s u_{a_i a_{s+1} \dots a_N} + \sum_{i < j=1}^s u_{a_i a_j a_{s+1} \dots a_N} + \dots + u_{a_1 \dots a_N}, \quad (7)$$

or, in compact form,

$$w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(\alpha)} = \sum_{p=1}^s \sum_{\mu_1 < \dots < \mu_p=1}^s \sum_{\nu_1 < \dots < \nu_\alpha=s+1}^N u_{a_{\mu_1} \dots a_{\mu_p} a_{\nu_1} \dots a_{\nu_\alpha}}. \quad (8)$$

Note that the potentials for the separated systems, $w_{a_1 \dots a_s}$ and $w_{a_{s+1} \dots a_N}$, are given by expressions like equation (1) but with sums running from 1 to s and from $s+1$ to N respectively, and one may include $\alpha = 0$ by realizing that $w_{a_1 \dots a_s} \equiv w_{a_1 \dots a_s, a_{s+1} \dots a_N}^{(0)}$.

Now we set out to derive an equation for the distribution function, equation (2), by taking the gradient $\nabla_{\mathbf{r}} \equiv \partial/\partial \mathbf{r}$ of $f_{a_1 \dots a_s}$ with respect to any coordinate a_s , e. g., \mathbf{r}_1 and using for $w_{a_1 \dots a_N}$ the above decomposition. The second term in equation (4), $w_{a_{s+1} \dots a_N}$, does not contribute to this partial derivative, and with equation (8) we immediately find

$$\nabla_{\mathbf{r}_1} f_{a_1 \dots a_s} + f_{a_1 \dots a_s} \nabla_{\mathbf{r}_1} \beta w_{a_1 \dots a_s} + \sum_{p=1}^s \sum_{\mu_1 < \dots < \mu_p=1}^s \sum_{\alpha=1}^{N-s} \sum_{\nu_1 < \dots < \nu_\alpha=s+1}^N \frac{1}{V^\alpha} \int d\mathbf{r}_{\nu_1} \dots d\mathbf{r}_{\nu_\alpha} f_{a_1 \dots a_s a_{\nu_1} \dots a_{\nu_\alpha}} \nabla_{\mathbf{r}_1} \beta u_{a_{\mu_1} \dots a_{\mu_p} a_{\nu_1} \dots a_{\nu_\alpha}} = 0, \quad (9)$$

where the higher distribution functions $f_{a_1 \dots a_s a_{\nu_1} \dots a_{\nu_\alpha}}$ for $s + \alpha$ particles have been introduced under the 3α -fold integral; to be precise, similar to equation (2) for $\alpha < N - s$ and $f_{a_1 \dots a_N} = (V^N/Q_N) \exp(-\beta w_{a_1 \dots a_N})$ for $\alpha = N - s$, i. e., equation (9) is a coupled set of integro-differential equations that exactly determines $f_{a_1 \dots a_s}$ for $2 \leq s \leq N - 1$. While in the case of mere two-body interaction the two-particle distribution couples to that for three particles, and so on, the general many-body interaction, equation (1), produces a coupling of $f_{a_1 \dots a_s}$ to the whole sequence of *all* higher distribution functions.

Usually one is only interested in the distributions of few particles up to, let's say, $s = 4$ and, therefore, wants to solve equation (9) for $s \ll N$. On this condition we can extend the range of the α summations over the ν 's from $s + 1 \dots N$ to $1 \dots N$, and then apply the following relation for any function $\mathcal{G}_{a_1 a_2 \dots}$, that solely depends on the species, to replace sums over particle numbers with sums over particle species,

$$\sum_{\lambda_1 \neq \dots \neq \lambda_\alpha = 1}^N \mathcal{G}_{a_{\lambda_1} \dots a_{\lambda_\alpha}} = \sum_{a_1, \dots, a_\alpha} N_{a_1} \dots N_{a_\alpha} \mathcal{G}_{a_1 \dots a_\alpha} + O(N^{\alpha-1}), \quad (10)$$

e. g.,

$$\sum_{i=1}^N \mathcal{G}_{a_i} = \sum_a N_a \mathcal{G}_a, \quad (11)$$

$$\sum_{i \neq j=1}^N \mathcal{G}_{a_i a_j} = \sum_{a,b} N_a N_b \mathcal{G}_{ab} - \sum_a N_a \mathcal{G}_{aa}, \quad (12)$$

$$\sum_{i \neq j \neq k=1}^N \mathcal{G}_{a_i a_j a_k} = \sum_{a,b,c} N_a N_b N_c \mathcal{G}_{abc} - 3 \sum_{a,b} N_a N_b \mathcal{G}_{aab} + 2 \sum_a N_a \mathcal{G}_{aaa}. \quad (13)$$

The contributions from equation (10) of the orders $N^{\alpha-1}, N^{\alpha-2}, \dots, N$ will vanish when they are divided by V^α and the thermodynamic limit is performed for $N_a, V \rightarrow \infty$, whereas the partial densities $n_a = N_a/V$ remain finite. In this way one arrives at the famous BBGKY hierarchy of equations for $f_{a_1 \dots a_s}$ in the generalized version

$$\begin{aligned} & \nabla_{\mathbf{r}_1} f_{a_1 \dots a_s} + f_{a_1 \dots a_s} \nabla_{\mathbf{r}_1} \beta w_{a_1 \dots a_s} + \sum_{\alpha=1}^{N-s} \frac{1}{\alpha!} \sum_{a_{s+1}} \dots \sum_{a_{s+\alpha}} n_{a_{s+1}} \dots n_{a_{s+\alpha}} \\ & \times \int d\mathbf{r}_{s+1} \dots d\mathbf{r}_{s+\alpha} f_{a_1 \dots a_{s+\alpha}} \nabla_{\mathbf{r}_1} \beta w_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}} = 0 \end{aligned} \quad (14)$$

which takes into account many-body interactions. The second term in equation (14) comes from the direct interaction among the s particles via $w_{a_1 \dots a_s}$, the third term describes the collective influence of the $N - s$ particles on the former, where the potential

$$w_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}} = \sum_{p=1}^s \sum_{\mu_1 < \dots < \mu_p=1}^s u_{a_{\mu_1} \dots a_{\mu_p} a_{s+1} \dots a_{s+\alpha}} \quad (15)$$

differs from equation (8) in that the α particles are now those of species $a_{s+1}, \dots, a_{s+\alpha}$ at positions $\mathbf{r}_{s+1}, \dots, \mathbf{r}_{s+\alpha}$ and no longer a varying choice from the $N - s$ particles,

$$w_{a_1 \dots a_s, a_{s+1}} = \sum_{i=1}^s u_{a_i a_{s+1}} + \sum_{i < j=1}^s u_{a_i a_j a_{s+1}} + \dots + u_{a_1 \dots a_s a_{s+1}}, \quad (16)$$

$$w_{a_1 \dots a_s, a_{s+1} a_{s+2}} = \sum_{i=1}^s u_{a_i a_{s+1} a_{s+2}} + \dots + u_{a_1 \dots a_s a_{s+1} a_{s+2}}, \quad (17)$$

$$\begin{aligned} & \vdots \\ w_{a_1 \dots a_s, a_{s+1} \dots a_N} &= \sum_{i=1}^s u_{a_i a_{s+1} \dots a_N} + \sum_{i < j=1}^s u_{a_i a_j a_{s+1} \dots a_N} + \dots + u_{a_1 \dots a_s}. \end{aligned} \quad (18)$$

Though equation (14) has been derived for small s , the distribution $f_{a_1 \dots a_s}$ nevertheless couples to $f_{a_1 \dots a_{s+1}}, \dots, f_{a_1 \dots a_N}$ as in equation (9), but seeing that $f_{a_1 \dots a_{s+\alpha}}$ is associated with the density power n^α , one might hope to decouple the hierarchy by expanding the distribution functions at low densities. Such a procedure will only work without difficulty if all the interactions are strictly short-ranged, i. e., the potentials drop off more rapidly than $1/r_{ij}^3$ for $r_{ij} \equiv |\mathbf{r}_i - \mathbf{r}_j| \rightarrow \infty$; otherwise some of the resulting integrals will diverge in the thermodynamic limit. In the system under consideration, however, each particle of species a bears a charge q_a , and so the most characteristic type of interaction is the long-range, two-body Coulomb interaction via the potential $v_{ab}(r_{ij}) = q_a q_b / r_{ij}$, which is part of u_{ab} and, hence, also of $w_{a_1 \dots a_s}$ and $w_{a_1 \dots a_s, a_{s+1}}$. Because the higher components u_{abc}, u_{abcd}, \dots are supposed to be short-ranged, v_{ab} is the only long-range potential at all, and $u_{ab} = v_{ab} + v'_{ab}$ can be written as the sum of v_{ab} and a short-range part v'_{ab} . In the same manner, we split up $w_{a_1 \dots a_s}$ and $w_{a_1 \dots a_s, a_{s+1}}$, thereby defining the short-range potentials $w'_{a_1 \dots a_s}$ and $w'_{a_1 \dots a_s, a_{s+1}}$,

$$w_{a_1 \dots a_s} = \sum_{i < j=1}^s v_{a_i a_j} + w'_{a_1 \dots a_s}, \quad (19)$$

$$w'_{a_1 \dots a_s} = \sum_{i < j=1}^s v'_{a_i a_j} + \sum_{i < j < k=1}^s u_{a_i a_j a_k} + \dots + u_{a_1 \dots a_s}, \quad (20)$$

$$w_{a_1 \dots a_s, a_{s+1}} = \sum_{i=1}^s v_{a_i a_{s+1}} + w'_{a_1 \dots a_s, a_{s+1}}, \quad (21)$$

$$w'_{a_1 \dots a_s, a_{s+1}} = \sum_{i=1}^s v'_{a_i a_{s+1}} + \sum_{i < j=1}^s u_{a_i a_j a_{s+1}} + \dots + u_{a_1 \dots a_s a_{s+1}}. \quad (22)$$

At this point of our derivation, screening of the Coulomb potential is introduced, for which we will utilize the following integral equation [1] in two opposite directions,

$$\beta v_{ab} - \beta \tilde{v}_{ab} - \sum_c n_c \int d\mathbf{r}_3 \beta v_{ac} \beta \tilde{v}_{bc} = 0, \quad (23)$$

that relates the bare potential v_{ab} and the screened potential \tilde{v}_{ab} with each other. The traditional “forward” use [9] consists in converting equation (23) into a partial differential equation, the linearized Poisson-Boltzmann equation, and solving it by the Fourier transform method to get the well-known expression $\tilde{v}_{ab}(r_{ij}) = q_a q_b \exp(-\kappa r_{ij}) / r_{ij}$, where the Debye-Hückel parameter $\kappa = \sqrt{4\pi\beta \sum_a n_a q_a^2}$ plays the role of the inverse classical screening length, as usual. Vice versa, one may regard \tilde{v}_{ab} as given quantity and go “backwards” to substitute for the Coulomb potential occurring twice in the BBGKY hierarchy, equation (14), the series expansion $\beta v_{ab} = \lim_{N \rightarrow \infty} \sum_{m=0}^{N-2} G_{ab}^{(m)}$ [3,10], the terms of which are found from an iteration of the screening equation, equation (23),

$$G_{ab}^{(0)} = -g_{ab}, \quad G_{ab}^{(m)} = - \sum_c n_c \int d\mathbf{r}_3 G_{ac}^{(m-1)} g_{bc}, \quad m > 0, \quad (24)$$

so that

$$\beta v_{ab} = -g_{ab} + \sum_c n_c \int d\mathbf{r}_3 g_{ac} g_{bc} - \sum_{c,d} n_c n_d \int d\mathbf{r}_3 d\mathbf{r}_4 g_{ac} g_{bd} g_{cd} + \dots, \quad (25)$$

with $g_{ab} = -\beta \tilde{v}_{ab}$ being the correlation function in the Debye-Hückel approximation.

In the limit of infinite dilution, $n_a \rightarrow 0$ for all species, the hierarchy reduces to the first two terms of equation (14) and then has the simple solution $f_{a_1 \dots a_s} \propto \exp(-\beta w_{a_1 \dots a_s})$. This suggests constructing an ansatz for $f_{a_1 \dots a_s}$ at *finite* density in the form [9]

$$f_{a_1 \dots a_s} = C_{a_1 \dots a_s} \exp \left[-\beta \left(\sum_{i < j=1}^s \tilde{v}_{a_i a_j} + w'_{a_1 \dots a_s} \right) \right], \quad (26)$$

where screening directly enters through \tilde{v}_{ab} that replaces $v_{ab} = \lim_{\kappa \rightarrow 0} \tilde{v}_{ab}$ in $w_{a_1 \dots a_s}$, equation (19), and other collective effects are handled by allowing the coefficient $C_{a_1 \dots a_s}$ to depend on the particles' densities under the constraint $\lim_{n_a \rightarrow 0} C_{a_1 \dots a_s} = 1$. Inserting equation (26) into the full BBGKY hierarchy, with the term for $\alpha = 1$ taken separately, and dividing by the exponential with the help of $w'_{a_1 \dots a_{s+1}} - w'_{a_1 \dots a_s} = w'_{a_1 \dots a_s, a_{s+1}}$ and

$$w'_{a_1 \dots a_{s+\alpha}} - w'_{a_1 \dots a_s} = w'_{a_{s+1} \dots a_{s+\alpha}} + \sum_{\lambda=s+1}^{s+\alpha} w'_{a_1 \dots a_s, a_\lambda} + \sum_{p=2}^{\alpha} \sum_{\lambda_1 < \dots < \lambda_p = s+1}^{s+\alpha} w_{a_1 \dots a_s, a_{\lambda_1} \dots a_{\lambda_p}}$$

for $\alpha > 1$, leads to coupled equations for $C_{a_1 \dots a_s}$ which are free of the bare potential,

$$\begin{aligned} & \nabla_{\mathbf{r}_1} C_{a_1 \dots a_s} + C_{a_1 \dots a_s} \nabla_{\mathbf{r}_1} \sum_{m=1}^{N-s} \sum_{i < j=1}^s G_{a_i a_j}^{(m)} + \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} C_{a_1 \dots a_{s+1}} \\ & \times \exp(-\beta \tilde{w}_{a_1 \dots a_s, a_{s+1}}) \nabla_{\mathbf{r}_1} \left(\sum_{m=1}^{N-s-1} \sum_{i=1}^s G_{a_i a_{s+1}}^{(m)} + \beta \tilde{w}_{a_1 \dots a_s, a_{s+1}} \right) \end{aligned}$$

$$\begin{aligned}
 & + \sum_{\alpha=2}^{N-s} \frac{1}{\alpha!} \sum_{a_{s+1}} \cdots \sum_{a_{s+\alpha}} n_{a_{s+1}} \cdots n_{a_{s+\alpha}} \int d\mathbf{r}_{s+1} \cdots d\mathbf{r}_{s+\alpha} C_{a_1 \dots a_{s+\alpha}} \\
 & \times \exp \left[-\beta \left(\sum_{\lambda=s+1}^{s+\alpha} \tilde{w}_{a_1 \dots a_s, a_\lambda} + \sum_{p=2}^{\alpha} \sum_{\lambda_1 < \dots < \lambda_p = s+1}^{s+\alpha} w_{a_1 \dots a_s, a_{\lambda_1} \dots a_{\lambda_p}} \right. \right. \\
 & \left. \left. + \tilde{w}_{a_{s+1} \dots a_{s+\alpha}} \right) \right] \nabla_{\mathbf{r}_1} \beta w_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}} = 0. \tag{27}
 \end{aligned}$$

The screened composite potentials in equation (27), $\tilde{w}_{a_{s+1} \dots a_{s+\alpha}}$ and $\tilde{w}_{a_1 \dots a_s, a_{s+1}}$, originate from the unscreened ones, $w_{a_{s+1} \dots a_{s+\alpha}}$ and $w_{a_1 \dots a_s, a_{s+1}}$, with \tilde{v}_{ab} instead of v_{ab} ,

$$\tilde{w}_{a_{s+1} \dots a_{s+\alpha}} = \sum_{i < j = s+1}^{s+\alpha} \tilde{v}_{a_i a_j} + w'_{a_{s+1} \dots a_{s+\alpha}} \tag{28}$$

$$= \sum_{i < j = s+1}^{s+\alpha} \tilde{u}_{a_i a_j} + \sum_{i < j < k = s+1}^{s+\alpha} u_{a_i a_j a_k} + \cdots + u_{a_{s+1} \dots a_{s+\alpha}} \tag{29}$$

and

$$\tilde{w}_{a_1 \dots a_s, a_{s+1}} = \sum_{i=1}^s \tilde{v}_{a_i a_{s+1}} + w'_{a_1 \dots a_s, a_{s+1}} \tag{30}$$

$$= \sum_{i=1}^s \tilde{u}_{a_i a_{s+1}} + \sum_{i < j = 1}^s u_{a_i a_j a_{s+1}} + \cdots + u_{a_1 \dots a_s a_{s+1}}, \tag{31}$$

where the two-body potential $\tilde{u}_{ab} = \tilde{v}_{ab} + v'_{ab}$ is the screened analogue to u_{ab} .

3. The virial expansion of the distribution functions

As we learnt in the preceding section, equation (27) holds for a many-particle system with two-body Coulomb interaction and additional short-range interactions between two and more particles. Since screening has removed all long-range components, the hierarchy now only contains screened and short-range potentials, \tilde{v}_{ab} , v'_{ab} , u_{abc} , \dots , and thus can be decoupled by doing the virial expansion $C_{a_1 \dots a_s} = \sum_{m=0}^{N-s} C_{a_1 \dots a_s}^{(m)}$ that is very similar to the one above for βv_{ab} . A careful analysis of its structure clearly reveals that the coefficient $C_{a_1 \dots a_s}^{(m)}$, for $m > 0$, includes the factor $n_{a_{s+1}} \dots n_{a_{s+m}}$, i. e., disregarding at the moment the functional dependence upon κ , it is formally of the density order n^m , and the same correspondingly applies to $G_{ab}^{(m)}$. This provides the following recipe how one obtains an equation for $C_{a_1 \dots a_s}^{(k)}$: introduce the auxiliary parameter γ and assign it to each density in equation (27) occurring as a factor (i. e., *not* to κ), multiply the terms and collect up those which belong to γ^k . The result reads

$$\nabla_{\mathbf{r}_1} C_{a_1 \dots a_s}^{(k)} + \sum_{m=1}^k \left(\nabla_{\mathbf{r}_1} G_{a_1 \dots a_s}^{(m)} \right) C_{a_1 \dots a_s}^{(k-m)}$$

$$\begin{aligned}
& - \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left[\left(\nabla_{\mathbf{r}_1} H_{a_1 \dots a_s, a_{s+1}} \right) C_{a_1 \dots a_{s+1}}^{(k-1)} \right. \\
& - \sum_{m=1}^{k-1} \left(\nabla_{\mathbf{r}_1} G_{a_1 \dots a_s, a_{s+1}}^{(m)} \right) \left(H_{a_1 \dots a_s, a_{s+1}} + 1 \right) C_{a_1 \dots a_{s+1}}^{(k-1-m)} \left. \right] \\
& - \sum_{\alpha=2}^k \frac{1}{\alpha!} \sum_{a_{s+1}} \dots \sum_{a_{s+\alpha}} n_{a_{s+1}} \dots n_{a_{s+\alpha}} \int d\mathbf{r}_{s+1} \dots d\mathbf{r}_{s+\alpha} \left(\nabla_{\mathbf{r}_1} H_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}} \right) \\
& \times \prod_{p=1}^{\alpha-1} \prod_{\lambda_1 < \dots < \lambda_p = s+1}^{s+\alpha} \left(H_{a_1 \dots a_s, a_{\lambda_1} \dots a_{\lambda_p}} + 1 \right) \left(H_{a_{s+1} \dots a_{s+\alpha}} + 1 \right) C_{a_1 \dots a_{s+\alpha}}^{(k-\alpha)} = 0, \quad (32)
\end{aligned}$$

and has been cast in this highly compact form by using sums over $G_{ab}^{(m)}$, equation (24),

$$G_{a_1 \dots a_s}^{(m)} = \sum_{i < j=1}^s G_{a_i a_j}^{(m)} \quad \text{and} \quad G_{a_1 \dots a_s, a_{s+1}}^{(m)} = \sum_{i=1}^s G_{a_i a_{s+1}}^{(m)}, \quad (33)$$

and Mayer cluster functions for the composite potentials, equations (29), (31), (15), $\alpha > 1$,

$$H_{a_{s+1} \dots a_{s+\alpha}} = \exp(-\beta \tilde{w}_{a_{s+1} \dots a_{s+\alpha}}) - 1, \quad (34)$$

$$H_{a_1 \dots a_s, a_{s+1}} = \exp(-\beta \tilde{w}_{a_1 \dots a_s, a_{s+1}}) - 1, \quad (35)$$

$$H_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}} = \exp(-\beta w_{a_1 \dots a_s, a_{s+1} \dots a_{s+\alpha}}) - 1. \quad (36)$$

Unlike the truncated equation (3.6) in [3], equation (32) displays in its last two lines the *general* term needed for the calculation of $C_{a_1 \dots a_s}^{(k)}$, $k > 2$, and therefore yields, at least in principle, the complete series of virial coefficients for s particles at the order $k = 0, \dots, N - s$. As a consequence of the screened virial, or cluster, expansion of $C_{a_1 \dots a_s}$, the sum over α is now cut off at k , and so $C_{a_1 \dots a_s}^{(k)}$ couples to the coefficients for at most $s + k$ particles whose order is lowered to $k - 1, k - 2, \dots, 0$. Then, it is obvious to solve equation (32) step by step from $k = 0$ to the desired order, where the solution must satisfy the boundary condition for vanishing particle correlations at infinity, $\lim_{r_{\mu\nu} \rightarrow \infty} C_{a_1 \dots a_s}^{(k)} = \delta_{k,0}$ ($\mu < \nu = 1, \dots, s$). At zeroth order, $k = 0$, equation (32) collapses to $\nabla_{\mathbf{r}_1} C_{a_1 \dots a_s}^{(0)} = 0$, and in view of the boundary condition we have at once $C_{a_1 \dots a_s}^{(0)} = 1$.

Although equation (32) would also permit to be treated at higher orders without too much effort, we will restrict ourselves to the first two non-trivial coefficients $C_{a_1 \dots a_s}^{(1)}$ and $C_{a_1 \dots a_s}^{(2)}$. Let $k = 1$, and the first-order coefficient $C_{a_1 \dots a_s}^{(1)}$ obeys the equation

$$\nabla_{\mathbf{r}_1} C_{a_1 \dots a_s}^{(1)} + \nabla_{\mathbf{r}_1} \left(G_{a_1 \dots a_s}^{(1)} - \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} H_{a_1 \dots a_s, a_{s+1}} \right) = 0, \quad (37)$$

from which the result of integration is evident while the integration constant can be derived as follows. We consider the integral over the cluster function $H_{a_1 \dots a_s, a_{s+1}}$,

equation (35), with respect to \mathbf{r}_{s+1} , depending on the $\binom{s}{2} = \frac{1}{2}s(s-1)$ relative coordinates $\{r_{ij}\} = r_{12}, \dots, r_{s-1s}$ that are simultaneously sent to infinity. In this limit, all the component potentials $u_{a_i a_j \dots a_{s+1}}$ in $\tilde{w}_{a_1 \dots a_s, a_{s+1}}$ with at least two variables $\mathbf{r}_i, \mathbf{r}_j, \dots$ do not contribute, i.e., only the first sum in equation (31) remains and $\int d\mathbf{r}_{s+1} H_{a_1 \dots a_s, a_{s+1}}$ approaches $\int d\mathbf{r}_{s+1} \hat{H}_{a_1 \dots a_s, a_{s+1}}$, where we meet the (asymptotic) cluster function

$$\hat{H}_{a_1 \dots a_s, a_{s+1}} = \exp\left(-\beta \sum_{i=1}^s \tilde{u}_{a_i a_{s+1}}\right) - 1. \quad (38)$$

According to Guernsey [11], one can identically rewrite $\hat{H}_{a_1 \dots a_s, a_{s+1}}$ in terms of products of Mayer functions $h_{ab} = \exp(-\beta \tilde{u}_{ab}) - 1$ for the screened pair potential \tilde{u}_{ab} ,

$$\hat{H}_{a_1 \dots a_s, a_{s+1}} = \sum_{i=1}^s h_{a_i a_{s+1}} + \sum_{i < j=1}^s h_{a_i a_{s+1}} h_{a_j a_{s+1}} + \dots + h_{a_1 a_{s+1}} h_{a_2 a_{s+1}} \dots h_{a_s a_{s+1}}. \quad (39)$$

Due to the localization of $h_{a_i a_{s+1}}$ around \mathbf{r}_i , the overlap between the different h 's in equation (39) vanishes at infinite particle separation, $r_{ij} \rightarrow \infty$, and again only the first sum is left over under the integral. Putting these steps together, we conclude that

$$\lim_{r_{\mu\nu} \rightarrow \infty} \int d\mathbf{r}_{s+1} H_{a_1 \dots a_s, a_{s+1}} = \int d\mathbf{r}_{s+1} \sum_{i=1}^s h_{a_i a_{s+1}} = \text{const}, \quad (40)$$

which is indeed a constant because of the spherical symmetry of the last integrand. The other term in equation (37), $G_{a_1 \dots a_s}^{(1)}$, gives no contribution to the integration constant for the same reason as before, and, with equation (40), $C_{a_1 \dots a_s}^{(1)}$ eventually becomes

$$C_{a_1 \dots a_s}^{(1)} = \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left(H_{a_1 \dots a_s, a_{s+1}} - \sum_{i=1}^s h_{a_i a_{s+1}} \right) - G_{a_1 \dots a_s}^{(1)}. \quad (41)$$

The determination of $C_{a_1 \dots a_s}^{(2)}$, the coefficient at second order, is more difficult as expected, and requires some additional steps. First, we specify equation (32) for $k = 2$,

$$\begin{aligned} & \nabla_{\mathbf{r}_1} C_{a_1 \dots a_s}^{(2)} + \left(\nabla_{\mathbf{r}_1} G_{a_1 \dots a_s}^{(1)} \right) C_{a_1 \dots a_s}^{(1)} + \nabla_{\mathbf{r}_1} G_{a_1 \dots a_s}^{(2)} - \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \\ & \times \left[\left(\nabla_{\mathbf{r}_1} H_{a_1 \dots a_s, a_{s+1}} \right) C_{a_1 \dots a_{s+1}}^{(1)} - \left(\nabla_{\mathbf{r}_1} G_{a_1 \dots a_s, a_{s+1}}^{(1)} \right) H_{a_1 \dots a_s, a_{s+1}} \right] \\ & - \frac{1}{2} \sum_{a_{s+1}} \sum_{a_{s+2}} n_{a_{s+1}} n_{a_{s+2}} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} \left(\nabla_{\mathbf{r}_1} H_{a_1 \dots a_s, a_{s+1} a_{s+2}} \right) \\ & \times \left(H_{a_1 \dots a_s, a_{s+1}} + 1 \right) \left(H_{a_1 \dots a_s, a_{s+2}} + 1 \right) \left(h_{a_{s+1} a_{s+2}} + 1 \right) = 0, \end{aligned} \quad (42)$$

where $\int d\mathbf{r}_{s+1} G_{a_1 \dots a_s, a_{s+1}}^{(1)} = \text{const}$ and $H_{a_{s+1} a_{s+2}} = h_{a_{s+1} a_{s+2}}$ have been used, cf. equations (33), (40), and (34). With equation (41) inserted for $C_{a_1 \dots a_s}^{(1)}$, and with the

two relations

$$\begin{aligned} H_{a_1 \dots a_{s+1}, a_{s+2}} - h_{a_{s+1} a_{s+2}} &= \\ &= H_{a_1 \dots a_s, a_{s+1} a_{s+2}} \left(H_{a_1 \dots a_s, a_{s+2}} + 1 \right) \left(h_{a_{s+1} a_{s+2}} + 1 \right) + H_{a_1 \dots a_s, a_{s+2}} \left(h_{a_{s+1} a_{s+2}} + 1 \right) \end{aligned}$$

and $G_{a_1 \dots a_s}^{(1)} + G_{a_1 \dots a_s, a_{s+1}}^{(1)} = G_{a_1 \dots a_{s+1}}^{(1)}$, we can bring equation (42) to the integrable form

$$\begin{aligned} &\nabla_{\mathbf{r}_1} C_{a_1 \dots a_s}^{(2)} + \nabla_{\mathbf{r}_1} \left\{ G_{a_1 \dots a_s}^{(2)} - \frac{1}{2} \left(G_{a_1 \dots a_s}^{(1)} \right)^2 \right. \\ &+ \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left(G_{a_1 \dots a_{s+1}}^{(1)} H_{a_1 \dots a_s, a_{s+1}} - G_{a_1 \dots a_s}^{(1)} \sum_{i=1}^s h_{a_i a_{s+1}} \right) \\ &- \frac{1}{2} \sum_{a_{s+1}} \sum_{a_{s+2}} n_{a_{s+1}} n_{a_{s+2}} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} \\ &\times \left[H_{a_1 \dots a_s, a_{s+1} a_{s+2}} \left(H_{a_1 \dots a_s, a_{s+1}} + 1 \right) \left(H_{a_1 \dots a_s, a_{s+2}} + 1 \right) \left(h_{a_{s+1} a_{s+2}} + 1 \right) \right. \\ &+ H_{a_1 \dots a_s, a_{s+1}} H_{a_1 \dots a_s, a_{s+2}} \left(h_{a_{s+1} a_{s+2}} + 1 \right) \\ &\left. \left. - H_{a_1 \dots a_s, a_{s+1}} \sum_{i=1}^s h_{a_i a_{s+2}} - H_{a_1 \dots a_s, a_{s+2}} \sum_{i=1}^s h_{a_i a_{s+1}} \right] \right\} = 0, \end{aligned} \quad (43)$$

the correctness of which is most easily verified backwards: taking the derivative in equation (43), employing equation (40) and the symmetry of the terms in the square brackets against the interchange $s+1 \leftrightarrow s+2$, we get a complete agreement with equation (42). The rest of the calculation is then almost as straightforward as for $C_{a_1 \dots a_s}^{(1)}$, and the same arguments as above lead to some new contributions to the integration constant,

$$\lim_{r_{\mu\nu} \rightarrow \infty} \int d\mathbf{r}_{s+1} G_{a_1 \dots a_s, a_{s+1}}^{(1)} H_{a_1 \dots a_s, a_{s+1}} = \int d\mathbf{r}_{s+1} \sum_{i=1}^s G_{a_i a_{s+1}}^{(1)} h_{a_i a_{s+1}}, \quad (44)$$

$$\begin{aligned} &\lim_{r_{\mu\nu} \rightarrow \infty} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} H_{a_1 \dots a_s, a_{s+1} a_{s+2}} \\ &\times \left(H_{a_1 \dots a_s, a_{s+1}} + 1 \right) \left(H_{a_1 \dots a_s, a_{s+2}} + 1 \right) \left(h_{a_{s+1} a_{s+2}} + 1 \right) \\ &= \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} \left(h_{a_{s+1} a_{s+2}} + 1 \right) \sum_{i=1}^s h_{a_i a_{s+1} a_{s+2}} \left(h_{a_i a_{s+1}} + 1 \right) \left(h_{a_i a_{s+2}} + 1 \right), \end{aligned} \quad (45)$$

$$\begin{aligned} &\lim_{r_{\mu\nu} \rightarrow \infty} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} H_{a_1 \dots a_s, a_{s+1}} H_{a_1 \dots a_s, a_{s+2}} \left(h_{a_{s+1} a_{s+2}} + 1 \right) \\ &= \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} \left(h_{a_{s+1} a_{s+2}} \sum_{i=1}^s h_{a_i a_{s+1}} h_{a_i a_{s+2}} + \sum_{i=1}^s h_{a_i a_{s+1}} \sum_{j=1}^s h_{a_j a_{s+2}} \right), \end{aligned} \quad (46)$$

besides those, from the last two terms in equation (43), already familiar from equation (40), with the three-particle Mayer function $h_{abc} = \exp(-\beta u_{abc}) - 1$. The final

result is

$$\begin{aligned}
 C_{a_1 \dots a_s}^{(2)} &= \frac{1}{2} \left(C_{a_1 \dots a_s}^{(1)} \right)^2 - \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left(G_{a_1 \dots a_s, a_{s+1}}^{(1)} H_{a_1 \dots a_s, a_{s+1}} - \sum_{i=1}^s G_{a_i a_{s+1}}^{(1)} h_{a_i a_{s+1}} \right) \\
 &+ \frac{1}{2} \sum_{a_{s+1}} \sum_{a_{s+2}} n_{a_{s+1}} n_{a_{s+2}} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} \\
 &\times \left\{ \left[H_{a_1 \dots a_s, a_{s+1} a_{s+2}} \left(H_{a_1 \dots a_s, a_{s+1}} + 1 \right) \left(H_{a_1 \dots a_s, a_{s+2}} + 1 \right) \right. \right. \\
 &\quad \left. \left. - \sum_{i=1}^s h_{a_i a_{s+1} a_{s+2}} \left(h_{a_i a_{s+1}} + 1 \right) \left(h_{a_i a_{s+2}} + 1 \right) \right] \left(h_{a_{s+1} a_{s+2}} + 1 \right) \right. \\
 &\quad \left. + h_{a_{s+1} a_{s+2}} \left(H_{a_1 \dots a_s, a_{s+1}} H_{a_1 \dots a_s, a_{s+2}} - \sum_{i=1}^s h_{a_i a_{s+1}} h_{a_i a_{s+2}} \right) \right\} - G_{a_1 \dots a_s}^{(2)}, \quad (47)
 \end{aligned}$$

where $C_{a_1 \dots a_s}^{(1)}$, equation (41), has been reintroduced to make this expression shorter.

4. Summary and comparisons

To summarize our paper, we derived the screened BBGKY hierarchy of equations, equation (27), for the reduced distribution of s charged, classical particles with long-range and many-body short-range interactions, and solved it for the first coefficients in the cluster expansion of $f_{a_1 \dots a_s}$ through second order, so that the calculation ends in

$$f_{a_1 \dots a_s} = \left(1 + C_{a_1 \dots a_s}^{(1)} + C_{a_1 \dots a_s}^{(2)} \right) \exp(-\beta \tilde{w}_{a_1 \dots a_s}). \quad (48)$$

The full expression (41) for $C_{a_1 \dots a_s}^{(1)}$ was obtained by Schmitz, equation (3.10) in [3], more than thirty years ago, but in contrast he failed in getting an equivalent result for $C_{a_1 \dots a_s}^{(2)}$, which was given by the present author only recently, see equation (6) and the discussion in [7]. We, therefore, regard the derivation of $C_{a_1 \dots a_s}^{(2)}$, equation (47), in the last section as the first *complete* approach to the distribution function at second order for the described physical system based on the BBGKY hierarchy.

Examples of the coefficients for $s = 2$ and 3, namely $C_{ab}^{(1)}$, $C_{ab}^{(2)}$, and $C_{abc}^{(1)}$, can be found in [12] and, in part, compared with Friedman's corresponding contributions in graphical representation [9] as far as they are shown in his figure 14.1. In the special case of pairwise interactions, $u_{a_1 \dots a_\lambda} \equiv 0$ if $\lambda > 2$, our expressions for $C_{a_1 \dots a_s}^{(1)}$ and $C_{a_1 \dots a_s}^{(2)}$ become identical to Schmitz' earlier results [13] as it should be; for the sake of convenience they are repeated here in our notation, especially with equation (38),

$$\begin{aligned}
 \hat{C}_{a_1 \dots a_s}^{(1)} &= \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left(\hat{H}_{a_1 \dots a_s, a_{s+1}} - \sum_{i=1}^s h_{a_i a_{s+1}} \right) - G_{a_1 \dots a_s}^{(1)}, \quad (49) \\
 \hat{C}_{a_1 \dots a_s}^{(2)} &= \frac{1}{2} \left(\hat{C}_{a_1 \dots a_s}^{(1)} \right)^2 - G_{a_1 \dots a_s}^{(2)}
 \end{aligned}$$

$$\begin{aligned}
& - \sum_{a_{s+1}} n_{a_{s+1}} \int d\mathbf{r}_{s+1} \left(G_{a_1 \dots a_s, a_{s+1}}^{(1)} \hat{H}_{a_1 \dots a_s, a_{s+1}} - \sum_{i=1}^s G_{a_i a_{s+1}}^{(1)} h_{a_i a_{s+1}} \right) \\
& + \frac{1}{2} \sum_{a_{s+1}} \sum_{a_{s+2}} n_{a_{s+1}} n_{a_{s+2}} \int d\mathbf{r}_{s+1} d\mathbf{r}_{s+2} h_{a_{s+1} a_{s+2}} \\
& \quad \times \left(\hat{H}_{a_1 \dots a_s, a_{s+1}} \hat{H}_{a_1 \dots a_s, a_{s+2}} - \sum_{i=1}^s h_{a_i a_{s+1}} h_{a_i a_{s+2}} \right). \tag{50}
\end{aligned}$$

The manner of reduction to these equations from equations (41) and (47) demonstrates that the effect of higher potential components on the distribution functions is not simply additive despite the structure of the direct potential, equation (1). Similar calculations using only pair potentials but with a slightly modified ansatz for $f_{a_1 \dots a_s}$ have been performed by Guernsey [11] and by Ebeling *et al.* [14]. Last not least, equations (49) and (50) coincide for $s = 2$ with the diagrams for the coefficients $\hat{C}_{ab}^{(1)}$ and $\hat{C}_{ab}^{(2)}$ of the binary distribution f_{ab} in the pioneering works by Meeron, equation (5.4) in [15], and by Yukhnovskii and his students [16–19], equation (2.64) in [20], way back to the 1950s. More recently, Holovko and Krienke [21] presented f_{ab} in a purely exponential form, their equations (21), (18), and (22), which after expansion also gets equal to our results.

The detailed knowledge of the distribution function gained in this article constitutes a firm basis for calculating thermodynamic properties. In accordance with the outline sketched in [22], a subsequent paper will be devoted to the derivation of the cluster expansion of the Helmholtz free energy up to the fourth cluster integral [12].

5. Acknowledgements

I would like to express my sincere gratitude to the people from the Institute for Condensed Matter Physics of the National Academy of Sciences of Ukraine in Lviv for their warm hospitality. In particular, I am thankful to Ihor M. Mryglod, Myroslav F. Holovko, Vasyl V. Ignatyuk, and Oleg V. Velychko. During the Workshop on Modern Problems of Soft Matter Theory in Lviv, Ukraine, on August 27–31, 2000, I enjoyed inspiring discussions with Ihor R. Yukhnovskii on the binary distribution function and the second virial coefficient for classical Coulomb systems.
